When their bathing gets interrupted, they decide to finish the encounter. They agree to a third round in the water and then head home. Clinical management of atrial fibrillation: the role of antiarrhythmic drugs. Atrial fibrillation (AF) is the most common sustained cardiac arrhythmia and is associated with a high mortality and morbidity. Of the three antiarrhythmic drugs available (amiodarone, propafenone, and flecainide), those with proven efficacy for both the maintenance of sinus rhythm (SR) and the prevention of AF recurrence are propafenone and amiodarone. Amiodarone has a much longer half-life, and thus a greater potential to prolong repolarization than propafenone. Both agents have proven efficacy in maintaining SR and preventing AF recurrence in patients with paroxysmal AF, and their efficacy in this regard have been evaluated in only a few studies. The doses recommended for both agents are within the accepted therapeutic range. Amiodarone may be preferred in patients with impaired left ventricular function, because amiodarone appears to be safer than propafenone in this regard. Further studies are

needed to evaluate the efficacy of these agents in patients with persistent AF, and in patients with underlying coronary disease, ischaemic heart disease, congestive heart failure, hypertension, and valvular heart disease./* * * Copyright 2016 gRPC authors.
